You see that type of behavior in other chart patterns.

Table 51.6 shows volume-related statistics.

Volume trend. Volume trends downward in more than two of every three rectangles. Does it matter if volume trends upward instead? In many chart pattern types, the answer is “not really.” They may show a preference, but the statistical performance difference is minor.

Rising/Falling volume. In bull markets after upward breakouts, rectangles with a rising volume trend *substantially* outperform those with a falling volume. Downward breakouts are mixed, and the performance difference isn't great, either.

Breakout day volume. Here again, bull markets with upward breakouts see substantially better performance if breakout day volume is light (below average). To those who warn of taking a position in a chart pattern showing low breakout volume, I say prove it. Yes, heavy breakout volume usually helps, but not all of the time and the push isn't as large as many suggest.

Table 51.7 shows how often price reaches a stop location. I split the rectangle and measured how often the search for the ultimate high or low resulted in price touching one of the three locations shown in the table.

For upward breakouts in bull markets, as an example, price returned to the top of the pattern 72% of the time. If you had placed a stop there, it would have closed out your trade in almost three of every four trades.
