Width. The results for width follow market conditions. Wide islands performed best in bull markets. Narrow islands did well in bear markets. I measured width from gap to gap, as you might expect, and all comparisons are against the median widths shown in the table.

Height and width combinations. Because bear markets have few samples when split into up or down breakouts and four combinations of height and width, let's ignore them.

Upward breakouts show the best performance if the pattern is both short and wide. That's odd because tall patterns usually do better than short ones. Downward breakouts behave with tall and wide patterns outperforming, just as their individual traits predict.

Table 45.6 shows volume-related statistics.

Volume trend. Island tops and bottoms have a downward volume trend, as measured between the two gaps. The receding trend agrees with most other chart pattern types.

Rising/Falling volume. In all columns, patterns with a rising volume trend outperform those with a falling volume trend. The performance differences are pronounced for island bottoms (upward breakouts).

Breakout day volume. Heavy breakout volume tends to push price along the breakout direction more than light volume, except in bear markets after downward breakouts (which prefer light volume).
