Rise between bottoms. In the past, traders used to look for a rise between the two bottoms of more than 10%, as measured from the lowest bottom low to the highest high between the two bottoms. That's an arbitrary value. I don't pay much attention to a minimum height except to say that taller patterns perform better than short ones.

For example, consider **Figure 26.2**, which shows a valid Adam & Adam double bottom (center pattern) and a potential one (upper left at ABC). The center Adam & Adam pattern has two narrow, V-shaped bottoms and volume that is higher on the left side than on the right.

Twin bottom AB (upper left of chart) does not have Adam-shaped bottoms. The bottom at B is wider and more rounded looking than what we expect to see in an Adam & Adam pattern. So this potential double bottom is an Adam & Eve pattern or perhaps an Eve & Eve.

The rise to C is just 4%. That's fine but well below the 10% (or higher) I like to see.

Bottom low price. From the lowest low on the left bottom to the low on the right, the price variation should be small. For example, do not try to assign double bottom status to the right bottom of the Adam & Adam in October and point D in Figure 26.2. Point D does not drop close enough to the right bottom to qualify it as a valid bottom.
