include in the tables.

Extension length. In Figure 70.3, the length of the extension is the move from C (the end of the uptrend on the right side of the V) to the breakout (D).

Yearly position, performance. I sorted the breakout price into where it fits in the yearly price range and mapped performance accordingly. The best performance occurs when the breakout is within a third of the yearly low for both bull and bear markets. This pattern works well for traders who like to bottom fish (buy near the yearly low, sell higher), but it doesn't work as well for momentum players (buy high, sell higher). I found that out the hard way (see Experience).

Throwback. A throwback happens more than half the time, but it's slower to unfold than usual. The round-trip for other chart pattern types is about 11 days. The extended V-bottom takes almost two weeks for the stock to return to the breakout price. By definition, a throwback must happen within a month.

The results suggest that you can make money if you're a nimble trader. Place a buy stop a penny above the breakout price and sell about a week later. On average, you could capture 9% to 14% if you trade it often enough and perfectly.
