Table 53.6 shows statistics related to roof volume.

Volume trend. I used linear regression to determine whether volume was rising or falling from the start to end of the roof. Most of the time, you'll see volume trending downward.

Rising/falling volume. Upward breakouts do best with a rising volume trend and downward breakouts show no significant performance difference.

Breakout day volume. For the breakout day volume, I compared the breakout day's volume with the prior 1-month average. Heavy volume on the breakout day propels a stock upward, but doesn't do anything for downward breakouts. More samples might change the results.

Table 53.7 shows how often price, after the breakout, hits the top, middle, or bottom of the roof. I don't show upward breakouts because I haven't yet taught my computer how to handle trendline breakouts.

For downward breakouts, I used the *highest high* between the breakout and the ultimate low and compared that to the roof's price.

For example, placing a stop at the top of a roof after a downward breakout would see the stop hit just 3% of the time on average. Often, this will happen during a pullback—within 2 weeks of the breakout. Placing a stop below the bottom of the pattern will trigger 65% of the time, but the loss will be much smaller than if the stop were placed in the middle or top of the roof.

Table 53.6 Volume Statistics

Description	Up Breakout	Down Breakout
Volume trend	66% down	72% down
Rising volume trend performance	38%	–15%
Falling volume trend performance	32%	–16%
Heavy breakout volume performance	38%	–15%
Light breakout volume performance	29%	–15%
