Number found. I found 995 cups in 645 stocks with the first cup in September 1991 and the most recent in January 2018. Only 913 of those were from bull markets, so that's what I reported on.

Reversal (R), continuation (C) occurrence. By definition, with price rising into the pattern and an upward breakout, a continuation of the prevailing price trend results.

Average rise. The average rise is yummy, but the median rise (not shown) is an earthbound 34%.

Standard & Poor's 500 change. I compared the rise in the index with the move from the date of the cup's breakout to ultimate high. The index underperformed the cup-with-handle pattern during the same time period.

Days to ultimate high. Because the rise is robust, it takes a long time for price to reach the ultimate high, about 10 months. The median time is half that, though.

How many change trend? Here's where the pattern really shines. Over two thirds of the patterns will see price rise by more than 20%. Very nice, indeed.

Table 21.3 shows failure rates. Cups show failure rates that climb rapidly as the maximum price rises. For example, 5% or 48 patterns see price fail to rise more than 5% after the breakout. An additional 68 patterns, combined with the prior 48, means 13% will fail to see price rise more than 10% after the breakout. Half the patterns will fail to see price rise more than 35%.

Even though the rise from one row to the next seems big, it's much better than for many other chart patterns.

Table 21.4 shows breakout-related statistics.

Breakout direction. By definition, if you don't have an upward breakout, then you're not looking at a cup with handle. A breakout happens when price closes above the right cup rim or handle high.

Yearly position, performance. When I saw the average rise of 238% for patterns within a third of the yearly low, I thought it was a typo. It's not, but it's based on just five samples. Even the 58% gain uses only 29 samples, so it's tiny, too. Most of the patterns will have breakouts within a third of the yearly high.
