Height and width combinations. You would think that three of the columns that have tall patterns outperforming and wide patterns outperforming would show the best performance for patterns both tall and wide. That's not the case, though. Each column has its own preference.

Table 66.6 shows volume-related statistics.

Volume trend. Nearly all of the time volume trends downward from the pattern start to the end, as verified using linear regression.

Rising/Falling volume. In three of four columns (the right column, again, is the exception), a falling volume trend sees the best performance.

Breakout day volume. Heavy breakout volume helps performance (except in bear markets with downward breakouts). I wonder why the right column is the renegade?

Table 66.7 shows how often price reaches a stop location, but because my computer doesn't calculate the stops for symmetricals properly, I removed the table.

Table 66.8 shows the performance over three decades but does not include bear markets (which only happened in the 2000s).

Performance over time. Performance of symmetrical triangles has decreased over the decades, from 41% during the 1990s to 29% in the 2010s (upward breakouts).

Downward breakouts also show performance has suffered, but not dramatically so (probably because the numbers are close to zero anyway. How low can they go?).
