Nested dictionaries are extremely useful for organizing complex financial data with multiple attributes and relationships.

Sets: Unique Collections for Specialized Analysis

What Are Sets?

Sets are collections of unique, unordered items. Think of a set like a membership list for an exclusive club—each member is included only once, and there's no particular ordering. In trading, sets are useful for:

- Tracking unique securities across multiple portfolios
- Identifying overlapping stocks between different strategies
- Filtering duplicate trade signals
- Performing mathematical set operations on security groups

Creating Sets: Collections of Unique Elements

Creating a set uses curly braces (like dictionaries, but without key-value pairs):

```
# A set of stock symbols
tech_stocks = {"AAPL", "MSFT", "GOOGL", "META", "AMZN"}

# Create a set from a list (removes duplicates)
traded_today = set(["AAPL", "MSFT", "AAPL", "TSLA", "MSFT"])
print(traded_today)  # {"AAPL", "MSFT", "TSLA"}

# An empty set (note: {} creates an empty dictionary, not a set)
new_watchlist = set()

```
