
Next, Exhibit 7.15 provides a sense of the range of possibilities for the dynamic asset allocation generated by ten-year automatic rolling ladders. Twenty random simulations are shown with thin lines, along with the tenth, fiftieth, and ninetieth percentiles across the distribution. The median stock allocation stays relatively close to its initial level with only slight upward drift. At the tenth percentile, the stock allocation falls dramatically as the growth portfolio is spent down to extend the bond ladder over time. The growth portfolio depletes by year fifteen. On the other hand, the growth portfolio grows dramatically at the ninetieth percentile, so that the stock
