8.3.3 Model Selection

By carefully selecting the most appropriate pre-trained LLM, you lay the groundwork for a successful fine-tuning process, ensuring the model is well-suited to your specific tasks and objectives.

In this case, you are selecting ChatGPT. However, in other chapters, you compare ChatGPT with Claude, Bing's Copilot and Google's Gemini. Each model had its strengths and weaknesses. You should choose the one most suitable for your purpose.

8.3.4 Training Setup

Setting up the training environment is crucial in fine-tuning a language model. It involves configuring the following components:

Software Libraries

Most LLMs like ChatGPT already have Python pre-loaded. In Python, to save time, you sometimes need to load libraries, which are collections of formulas for processing, analysing, and presenting data. You should install the latest stable versions of the necessary libraries to avoid potential issues during training.

GPU Resources

Training an LLM requires considerable computational power. You might be used to central processing units (CPUs) as the resource for this purpose, but AI requires resources from the graphic processing unit (GPU). These units can multi-task a lot better than CPUs.

Hyperparameters

Hyperparameters control the learning process of a model. Some of the common hyperparameters are:

- Learning Rate
- Batch Size
- Number of Epochs
