Standard & Poor's 500 change. This table shows the influence of the general market trend on performance. That's really hard to prove, but if the general market is rising, it tends to lift all boats. Similarly, a falling market sucks boats down. Notice that the S&P lost 5% in bear markets and pennants with downward breakouts in that market performed the best of the four columns.

Days to trend high or low. This measure shows the average time price took to reach the trend high or low after the breakout. On average, you can make 10% in about 2 weeks (bear market, up breakout) if you trade pennants perfectly and often enough. That's not too bad. Of course, you won't trade it perfectly and probably not 207 times, either, so your results will vary.

I removed **Table 48.3** because failure rates don't make much sense when you're looking at the move to the trend end versus the ultimate high or low (for other chart patterns).

Table 48.4 shows breakout-related statistics.

Breakout direction. The breakout direction favors upward breakouts in bull markets and downward breakouts in bear markets. I like how that makes intuitive sense, even though the percentages are close to random.
