Table 57.6 shows volume-related statistics.

Volume trend. I used linear regression to determine the volume trend. Ascending scallops frequently show a rising volume trend. Most chart pattern types show receding volume. Don't discard a scallop just because it has a downward volume trend.

Rising/Falling volume. Scallop performance varies depending on the volume trend, as the table shows. If volume is important to you, then consult the table to see which market and breakout direction will give you the best chance of a winning trade.

Breakout day volume. Heavy breakout volume propels a stock farther than a breakout on weak volume, according to the performance numbers in the table. I used the 30-day average (leading to, but not including the breakout day) as the separator between heavy and light.

Table 57.7 shows how often price reaches a stop location. Upward breakouts will see high rates of a stop being triggered if the stop is placed at the top of the scallop, and downward breakouts will see the bottom of the pattern triggering a stop frequently. That's common sense, of course.

Because an ascending scallop can be tall, you'll want to change the potential loss into a percentage of the current price. Many traders try to limit losses to 8%, so if you're predicting a loss of 25%, then either move the stop closer or consider picking a different stock. You might try using a volatility-based stop, too. See the Glossary for details.
