The combination of a tall and wide pattern does, indeed, give us the best performance. But you can't say that for downward breakouts in bear markets. Tall and wide patterns should perform best, but they come in second to tall and narrow patterns.

What can we learn about scallops by observing volume? Table 60.6 shows some answers.

Volume trend. Most chart pattern types will see receding volume across the pattern but there are exceptions, like scallops. They see volume trending upward most often. Does it matter? Only in bull markets after upward breakouts.

Rising/Falling volume, breakout day volume. Patterns with a rising volume trend in bull markets after upward breakouts see price rise an average of 50%. If breakout volume is heavy (above average), you'll see better performance, too. The other two columns don't seem to care much about volume.

Table 60.7 shows how often price reaches a stop location. Let's use the bull market, up breakout column as an example. If you place a stop at the top of the scallop, price on the way to the ultimate high will trigger the stop 80% of the time on average.

Tuck at the stop at the bottom of the pattern and price will trip it just 3% of the time. You read the other two columns the same way.
