2. Create helper functions for each strategy:
    - Functions that calculate relevant indicators
    - Functions that generate entry and exit signals
    - Functions that determine appropriate position sizing
3. Implement a strategy_combiner() function that:
    - Takes signals from all three strategies
    - Assigns weights to each strategy
    - Generates a combined signal based on weighted consensus
    - Handles conflicting signals appropriately
4. Create portfolio management functions:
    - calculate_exposure(): Determines total market exposure
    - manage_risk(): Adjusts position sizes based on volatility
    - generate_orders(): Converts signals into specific trading actions
5. Build a backtest_system() function that:
    - Takes historical price data as input
    - Applies all strategies individually and in combination
    - Tracks performance of each strategy and the combined approach
    - Generates performance reports comparing all approaches
6. Include default parameters for all functions, but allow customization
