

```
1. # Define a trade record tuple
2. trade = ("AAPL", "BUY", 100, 143.78)
3.
4. # Unpack into separate variables
5. symbol, direction, quantity, price = trade
6.
7. # Now you can use each component individually
8. print(f"Traded {quantity} shares of {symbol} at ${price}")
9.
```

This unpacking syntax is especially useful for working with financial data that naturally comes in fixed structures, like OHLC (Open, High, Low, Close) price data or trade records.

When to Use Tuples vs. Lists

Use tuples when:

- The data represents a collection of related values that should not change
- You want to ensure data integrity throughout your program
- You're creating keys for dictionaries (which must be immutable)

Use lists when:

- You need to add, remove, or modify elements after creation
- You're tracking data that changes over time
- You need operations like sorting or appending new items

Dictionaries: Mapping Financial Data
