

- Strategy parameters (parameter name → current setting)
- Market data (field name → current value)

Creating Dictionaries: Organizing Data by Keys

Creating a dictionary uses curly braces with key-value pairs separated by colons:

```

1. # A dictionary of stock positions
2. portfolio = {
3.     "AAPL": 100,
4.     "MSFT": 50,
5.     "GOOGL": 25,
6.     "AMZN": 30
7. }
8.
9. # A dictionary of security attributes
10. stock_data = {
11.     "symbol": "AAPL",
12.     "price": 145.86,
13.     "pe_ratio": 28.35,
14.     "dividend_yield": 0.62,
15.     "sector": "Technology"
16. }
17.
18. # An empty dictionary
19. new_positions = {}
20.

```

Keys must be immutable (strings, numbers, or tuples), while values can be any type of object, including lists, other dictionaries, or even functions.

Accessing Dictionary Values: Finding What You Need

Accessing dictionary values is done using the key in square brackets:

```

1. portfolio = {"AAPL": 100, "MSFT": 50, "GOOGL": 25}
2.
3. # Get Apple position

```
