

The `get()` method is particularly useful in trading applications, where you might need to check for the existence of keys without causing errors.

Modifying Dictionaries: Updating Your Financial Records

Unlike tuples, dictionaries are mutable and can be updated after creation:

```
1. portfolio = {"AAPL": 100, "MSFT": 50, "GOOGL": 25}
2.
3. # Add a new position
4. portfolio["TSLA"] = 15
5.
6. # Update an existing position
7. portfolio["AAPL"] = 120
8.
9. # Remove a position
10. del portfolio["MSFT"]
11.
12. # Clear all positions
13. portfolio.clear()
14.
```

This mutability makes dictionaries ideal for tracking continuously updating information like current portfolio positions or market data.

Dictionary Methods: Managing Complex Data

Dictionaries come with several helpful methods for working with their contents:

```
1. stock_data = {
2.     "symbol": "AAPL",
3.     "price": 145.86,
4.     "pe_ratio": 28.35,
5.     "sector": "Technology"
6. }
7.
8. # Get all keys
9. attributes = list(stock_data.keys()) # ["symbol", "price", "pe_ratio", "sector"]
10.
```
