

- Compare reactions across different asset classes
- Highlight statistically significant market responses

5. Design a pattern recognition component that:

- Identifies common reaction patterns (e.g., initial overreaction followed by reversal)
- Calculates the probability of different outcomes based on historical data
- Suggests potential trading approaches for future similar events

This project will give you experience working with financial data in the context of specific market events, a crucial skill for developing event-driven trading strategies. It combines data collection, cleaning, and analysis with real-world market dynamics, helping you understand how various assets respond to different types of information.

Both projects emphasize the practical application of the data handling techniques covered in Chapter 7, while preparing you for the more advanced analysis and strategy development covered in subsequent chapters.
