

5. Apply your optimization system to at least one multi-year dataset with clear regime changes (e.g., 2007-2023 with bull and bear markets)
6. Create comparative visualizations:
 - Performance of each optimization method (both in-sample and out-of-sample)
 - Runtime efficiency comparison (execution time vs. results quality)
 - Parameter stability across different validation periods
 - "Parameter landscape" visualizations showing performance across parameter space
7. Develop a weighted scoring system to rank parameter sets based on:
 - Risk-adjusted returns (Sharpe and Sortino ratios)
 - Maximum drawdown and recovery time
 - Performance consistency across market regimes
 - Out-of-sample performance retention
