

```
6.  
7. # Display new price  
8. print(stock_price) # Shows 145.4316
```

Notice how the variable `stock_price` is updated with a new value. This ability to change variable values is essential for tracking changing market conditions.

Data Types: Categorizing Financial Information

In financial markets, you deal with different kinds of information: prices (numbers with decimal points), trading volumes (whole numbers), stock symbols (text), and conditions like "market is open" (true/false). Python provides different data types to handle these diverse information categories.

Integers: Whole Numbers

Integers (or `int` in Python) are whole numbers without decimal points. In trading, they're perfect for representing:

- Number of shares
- Trading volume
- Days until expiration
- Count of trades

Creating an integer variable:

```
1. number_of_shares = 100  
2. trading_volume = 15750000  
3.
```

Floats: Decimal Numbers

Floating-point numbers (or `float`) include decimal points. They're essential for representing:

- Stock prices
-
