

```
1. # Market conditions
2. price_to_earnings = 15.3
3. dividend_yield = 2.5
4. recent_growth = 5.8
5. sector_is_technology = True
```

```
1. # Value investing criteria
2. is_value_stock = (price_to_earnings < 20) and (dividend_yield > 2)
3.
4. # Growth investing criteria
5. is_growth_stock = (recent_growth > 5) and sector_is_technology
6.
7. # Potential investment if it meets either criterion
8. potential_investment = is_value_stock or is_growth_stock
9.
10. print(potential_investment) # Shows True
```

Basic Input and Output: Communicating with Your Program

For a trading algorithm to be useful, it needs to communicate with you (the trader) and potentially with external systems. This is where input and output operations come in.

The `print()` Function: Displaying Information

The `print()` function is your basic tool for displaying information:

```
1. stock_symbol = "AAPL"
2. current_price = 142.58
3. shares_owned = 100
4.
5. print("Stock:", stock_symbol)
6. print("Current price:", current_price)
7. print("Position value:", current_price * shares_owned)
```
