

The language that once required specialized knowledge to learn is now designed for clarity and ease of use, opening doors that were previously closed to all but a select few.

This democratization of trading technology represents one of the most significant shifts in financial market history—and you're now part of that revolution.

Project 1: Stock Portfolio Summary Calculator

Objective: Create a simple Python program that allows users to input information about stocks in their portfolio and calculates key metrics to help them understand their overall investment position.

Requirements:

1. Ask the user to input information for 3 different stocks (symbol, purchase price, current price, and number of shares)
2. For each stock, calculate:
 - The total value of the position
 - The profit/loss in dollars
 - The profit/loss percentage
3. After collecting all stocks, display:
 - A summary of each stock's performance
 - The total portfolio value
 - The overall portfolio profit/loss in both dollars and percentage

This project will reinforce your understanding of variables, different data types (strings for symbols, floats for prices, integers for share counts), arithmetic operators for financial calculations, and formatted output to present results clearly.
