

```
6. if current_price <= stop_loss:
7.     print("Stop loss triggered - sell position to limit losses")
8. elif current_price >= target_price:
9.     print("Target price reached - sell position to take profits")
10. else:
11.     print("Maintain position - price between stop loss and target")
```

This example shows how traders use conditionals to automate a complete position management strategy.

The `elif` Statement: Multiple Decision Paths

Trading often involves more than binary decisions. For instance, you might want different actions for bullish, bearish, or neutral market conditions. The `elif` statement (short for "else if") handles these multiple condition paths:

```
1. rsi_value = 72 # Relative Strength Index
2.
3. if rsi_value > 70:
4.     print("Market potentially overbought - consider selling")
5. elif rsi_value < 30:
6.     print("Market potentially oversold - consider buying")
7. else:
8.     print("RSI in neutral zone - maintain current positions")
```

This code checks if the RSI (a popular technical indicator) suggests overbought conditions, oversold conditions, or neither, and recommends appropriate actions.

Here's a more comprehensive example that evaluates a stock based on multiple criteria:

```
1. price_to_earnings = 15.2
2. dividend_yield = 3.5
3. debt_to_equity = 0.8
4.
5. if price_to_earnings < 10 and dividend_yield > 4:
6.     print("Value opportunity: Low P/E with high dividend")
7. elif price_to_earnings > 30 and dividend_yield < 1:
```
