

```
13.     # Implementation would go here
14.     return rsi_value
```

This well-formatted function declaration follows PEP 8 guidelines with proper indentation, descriptive variable names, and clear documentation.

Real-World Applications: Putting Control Flow to Work

Now that we understand the basics of control flow, let's see how these concepts come together in real trading scenarios.

Example 1: A Simple Trend-Following System

This example combines conditionals and loops to implement a basic trend-following strategy:

```
1. # Sample price data for the last 20 days
2. prices = [105, 106, 107, 106, 105, 107, 108, 109, 110, 109,
3.          111, 112, 113, 114, 115, 116, 115, 116, 117, 118]
4.
5. # Calculate 5-day and 20-day moving averages
6. short_period = 5
7. long_period = 20
8.
9. short_ma = sum(prices[-short_period:]) / short_period
10. long_ma = sum(prices) / long_period
11.
12. # Trading decision based on moving average crossover
13. if short_ma > long_ma:
14.     print("Bullish signal: Short-term MA above Long-term MA")
15.     position = "Long"
16. else:
17.     print("Bearish signal: Short-term MA below Long-term MA")
18.     position = "Flat"
19.
20. # Simulate future days
21. new_prices = [119, 120, 118, 117, 116]
22.
23. for day, new_price in enumerate(new_prices, 1):
```
