

```

11. # Calculate total portfolio value
12. total_value = 0
13. for stock, data in portfolio.items():
14.     total_value += data["value"]
15.
16. print(f"Total portfolio value: ${total_value:,.2f}")
17.
18. # Check if rebalancing is needed
19. for stock, data in portfolio.items():
20.     current_percent = data["value"] / total_value * 100
21.     target_percent = data["target_percent"]
22.     difference = current_percent - target_percent
23.
24.     print(f"\n{stock}:")
25.     print(f"  Current allocation: {current_percent:.1f}%")
26.     print(f"  Target allocation: {target_percent:.1f}%")
27.
28.     if abs(difference) > 5: # Rebalance if more than 5% off target
29.         print(f"  REBALANCE NEEDED: {difference:+.1f}% from target")
30.
31.         if difference > 0:
32.             sell_amount = (data["value"] - (target_percent / 100 * total_value))
33.             print(f"  Sell ${sell_amount:,.2f} to reduce position")
34.         else:
35.             buy_amount = ((target_percent / 100 * total_value) - data["value"])
36.             print(f"  Buy ${buy_amount:,.2f} to increase position")
37.         else:
38.             print(f"  Within acceptable range of target")

```

This portfolio rebalancing algorithm:

1.  
Calculates the current value of each position
2.  
Compares current allocations to targets
3.  
Identifies positions that need adjustment
- 4.
