

As you continue your journey into algorithmic trading, you'll build increasingly complex decision trees and analysis loops. But no matter how sophisticated your strategies become, they'll rest on the foundation of control flow concepts we've covered in this chapter.

In the next chapter, we'll explore functions—reusable blocks of code that will help you organize your trading logic into modular, maintainable components. This will allow you to create even more powerful and flexible trading systems while keeping your code clean and manageable.

Remember Virtu Financial's remarkable streak of 1,237 consecutive profitable trading days? That wasn't magic—it was the power of well-designed algorithms making millions of precisely defined decisions through control flow structures just like the ones you've learned. With practice and persistence, you're now equipped to begin building similar decision-making logic into your own trading systems.

Project Question 3: Stock Screener System

Objective: Create a Python program that screens stocks based on multiple technical and fundamental criteria and categorizes them into different investment opportunities.

Requirements:

1. Create a list of dictionaries representing at least 8 stocks with the following attributes for each:
 - Symbol (string)
 - Current price (float)
 - 50-day moving average (float)
 - 200-day moving average (float)
