

- P/E ratio (float)
 - Debt-to-equity ratio (float)
 - Dividend yield (float)
 - Industry sector (string)
2. Implement a screening system that uses nested conditional statements to categorize each stock into one of these groups:
 - "Strong Buy" - Meets strict technical and fundamental criteria
 - "Moderate Buy" - Meets most criteria with some cautions
 - "Hold" - Mixed signals
 - "Sell" - Poor technical and fundamental indicators
 3. Use loops to iterate through each stock and apply your screening logic.
 4. For each stock, print a detailed analysis explaining why it received its specific rating.
 5. At the end, present a summary showing how many stocks fall into each category.

This project will help you practice using both conditional statements (if/elif/else) and loops to implement a realistic investment screening tool similar to what professional traders might use for initial stock filtering.

Project Question 4: Trading Strategy Backtester

Objective: Build a simple backtesting program that evaluates how a trading strategy would have performed over historical price data.
