

In breakouts, the price moves outside a defined resistance zone with an increase in volume. A breakout trader enters a long position after the stock price breaks above resistance.

So, a day trader can plan their intraday trades, hoping the same breakout move will continue, or look for better opportunities to opt for a long trade if it gives a pullback.

Below are some of the good resources to shortlist the breakout stocks in Indian and US markets.

Open Low and Open High Scanner

Open-Low and Open-High are the two powerful trading concepts for intraday traders. Please note that this concept should not be used independently and should be aligned with any other trading concept. However, day traders can use this information to screen the stocks immediately after the market opens and if the stocks align with their trading system, then they can take trades.

If the open-low or open-high sustains even after 15-minutes from the open, and if the chart satisfies all the entry rules as per the trading system, traders can plan long or short trades.
