

And let's say you work incredibly hard, scrape together \$5000 a year in savings and at age 15 start putting each year's savings into a managed share fund, which invests in the stock market. Along the way you earn a *nominal* 10 per cent return per year (the average return for the Aussie stock market, before inflation).

And then you STOP—by age 25—and never invest another cent.

That's you . . . now let's look at the bully.

She doesn't start as early as you.

She waits until she gets a *real* job—at age 25—before she starts investing.

Like you, she puts in \$5000 a year.

Unlike you, she doesn't stop. She continues, making her last investment after she turns 60.

All up, you put in \$50 000 (i.e. \$5000 for 10 years).

She puts in \$180 000 (\$5000 for 36 years).

Naturally, you'd think she'd have more than you, right?

Wrong.

Even though you've only put in less than one-third the amount she did, you end up with over 50 per cent more!

(You get \$2.7 million—she gets \$1.6 million.)

That's the power of compound interest. That's the power of time.

I've laid it out for you in a chart on [page](#).

This works every single time, and it's the safest and surest way to become incredibly wealthy.

So why don't more people do it?

Well, because it's kinda . . . boring. And in the first few years you hardly notice any improvement.
