

Notes

On-premise ERP

In an on-premise deployment model, the ERP software is installed and runs on the organisation's own servers and infrastructure, typically within its data centre or on-site facilities.

The costs associated with an on-premise ERP implementation include:

Perpetual software license fees: A one-time upfront cost for acquiring the ERP software license.

Hardware and infrastructure costs: Expenses related to purchasing and maintaining servers, storage, and other IT infrastructure required to run the ERP system.

Implementation costs: Similar to cloud-based implementations, these include configuration, data migration, integration, and training expenses.

Ongoing maintenance and support fees: Annual fees charged by the vendor for product updates, upgrades, and technical support.

On-premise ERP implementations require a higher initial investment but can be more cost-effective in the long run, particularly for organisations with stable and predictable operations. Additionally, on-premise solutions offer greater control over data security, customisation, and integration with legacy systems.

The decision between a cloud-based or on-premise deployment depends on factors such as internet connectivity, data security requirements, scalability needs, and the organisation's long-term cost projections. Consultants are vital in evaluating these factors, conducting comprehensive cost-benefit analyses, and recommending the most suitable deployment model aligned with the client's needs and constraints
