

Another critical aspect of data migration is the extraction and transformation of data from legacy systems. In many cases, the data structures and formats used in legacy systems may not align with the requirements of the new ERP system.

Organisations may need to develop custom scripts or programs to extract data from these systems and transform it into a format compatible with the ERP system's data model. This process often involves complex data mapping and transformation rules as well as thorough testing and validation to ensure data integrity.

Data Structures

Requirement of
ERP System

Organisations can proceed with the migration process once the data has been extracted, cleansed, and transformed. This typically involves loading the data into the ERP system using vendor-provided migration tools or custom-developed scripts. It is essential to conduct thorough testing and validation of the migrated data to ensure its accuracy and completeness before going live.
