

Integrating Existing Systems with the New ERP Platform

In addition to migrating data from legacy systems, organisations often need to integrate their existing systems and applications with the new ERP platform. This integration is crucial for ensuring seamless data flow, avoiding data silos, and enabling end-to-end business process automation across the organisation’s technology landscape.

Why is integration necessary?

Ensuring seamless data flow

Avoiding data silos

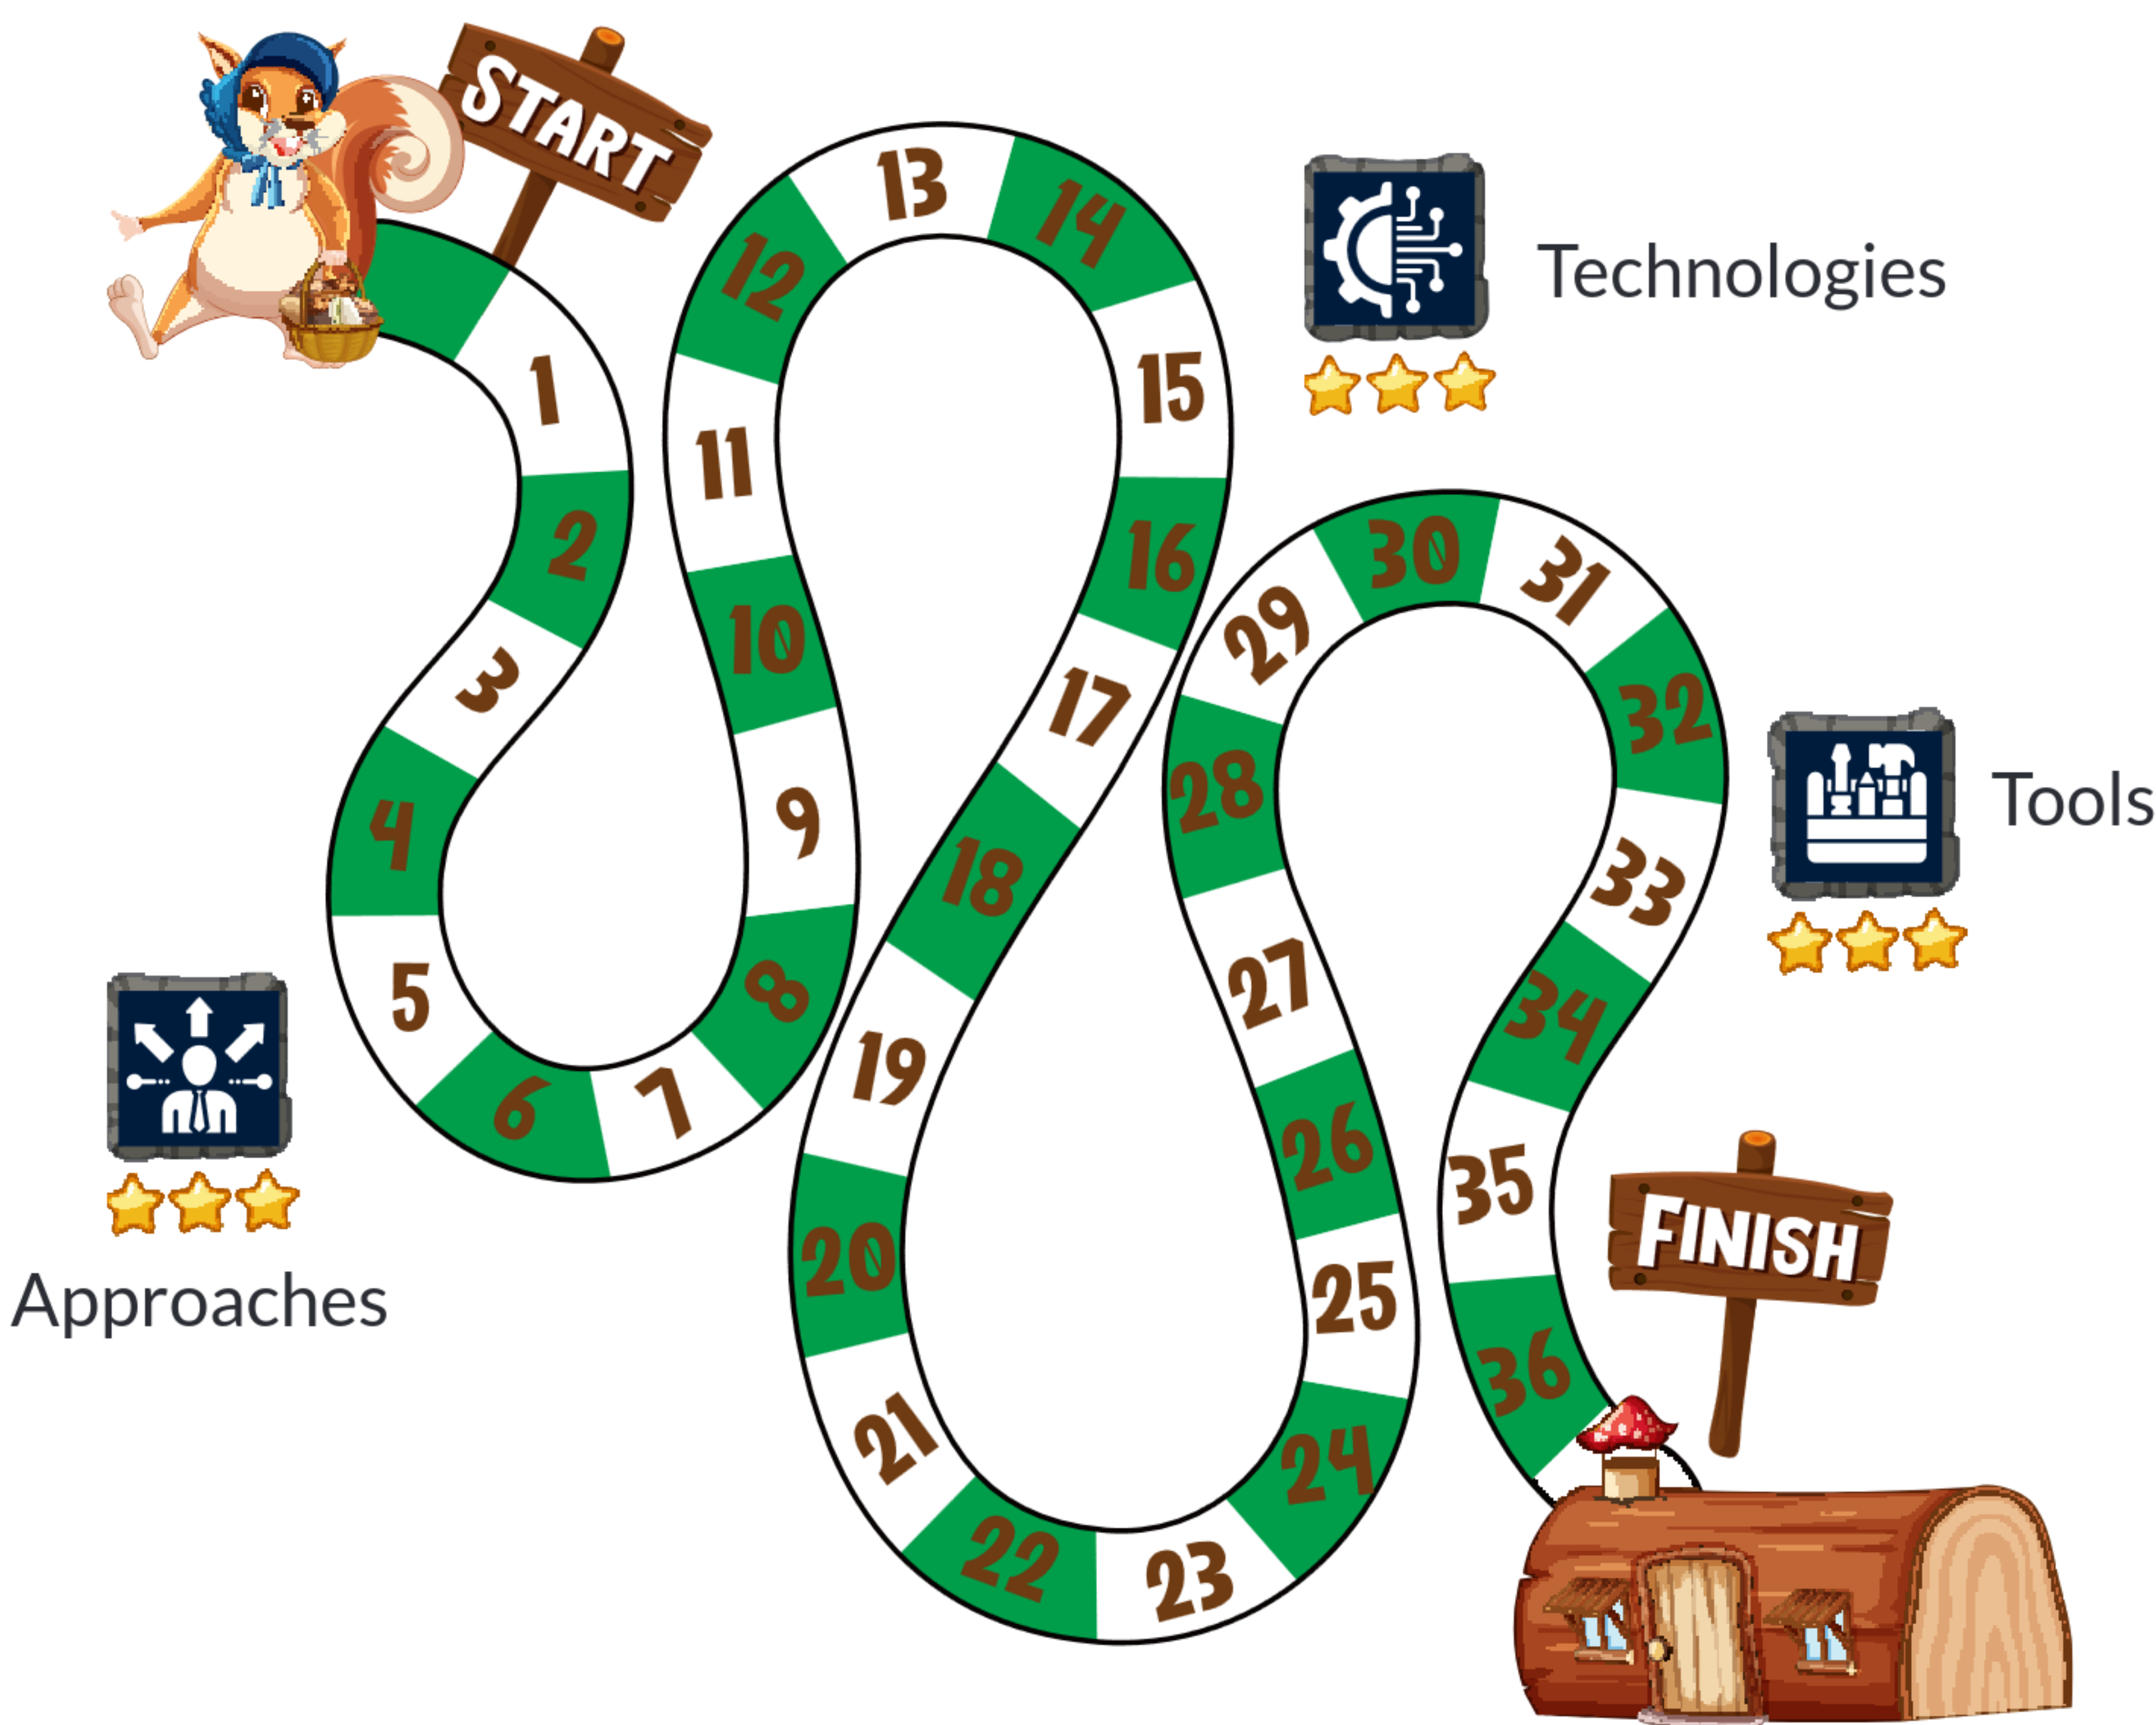

Enabling end-to-end business process automation

Integrating existing systems with the new ERP platform can be complex and challenging, as each system may have its own data formats, protocols, and interfaces. Consultants are pivotal in assessing the organisation’s existing system landscape, identifying potential integration points, and developing strategies to enable seamless integration with the new ERP platform.

One of the first steps in the integration process is to conduct a thorough inventory and assessment of the organisation’s existing systems. This includes identifying the systems’ functionalities, data models, interfaces, and integration capabilities.

Consultants should work closely with the organisation’s IT teams and subject matter experts to understand the business requirements and dependencies that drive the need for integration.

Develop an integration architecture and roadmap

Based on this assessment, consultants can develop an integration architecture and roadmap outlining the approach, technologies, and tools required to integrate the existing systems with the new ERP platform. This may involve building custom interfaces, developing data mapping rules, implementing middleware solutions, or leveraging existing integration platforms or tools.
