

Logical Functions

A key aspect of data analysis is evaluating logical conditions or criteria over the data. For this, Excel provides logical functions like:

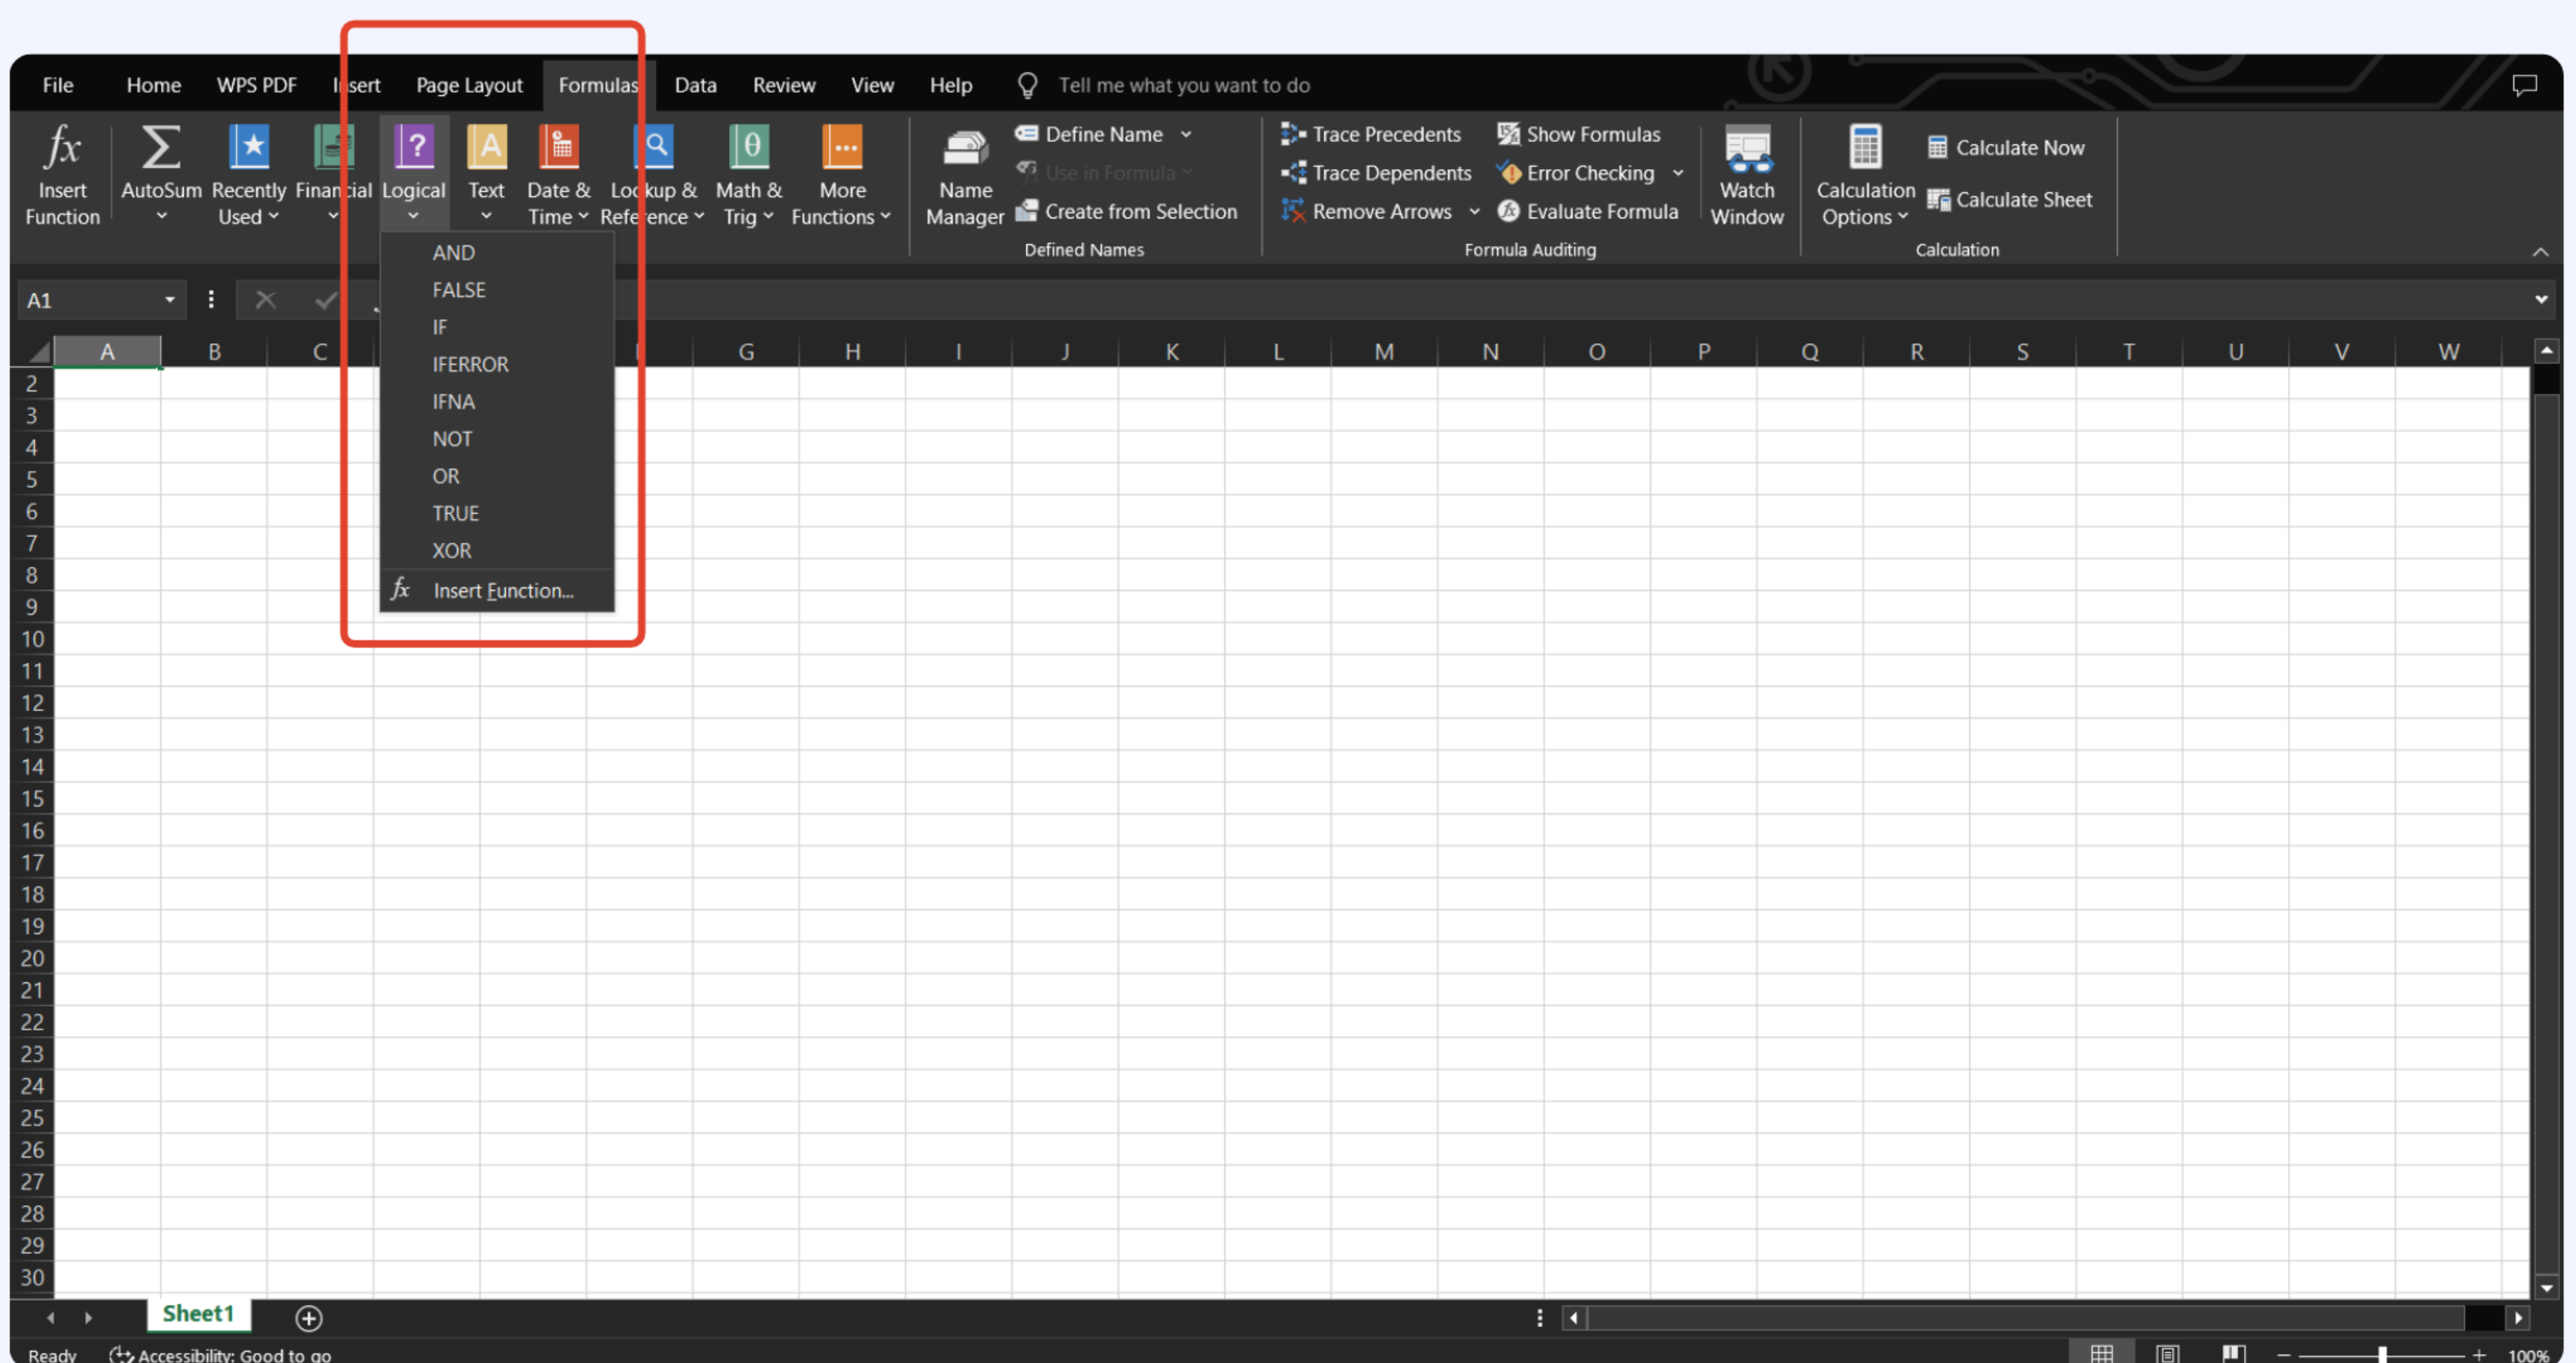

IF(): This is the most commonly used logical function. It checks for a specified condition and returns one true value and another if false.

AND(): Returns TRUE if all the conditions specified are true; otherwise, it returns FALSE.

OR(): Returns TRUE if any of the specified conditions is true; otherwise, it returns FALSE.

NOT(): Reverses the logic and returns the opposite Boolean value of what is evaluated.

IFERROR(): This option allows for the specification of a value to return if the formula evaluates an error instead of showing an error value.

Nesting these logical functions within each other using AND, OR, NOT, etc. conditions allows the creation of advanced decision-making rules and criteria over data in Excel.
