

Width. I used the median width as the separator between narrow and wide. Performance of wide patterns beats that of narrow ones. Consider trading only wide patterns.

Height and width combinations. Patterns both tall and wide perform as well or better than the other combinations in all four columns. For example, if you trade short and wide patterns in bull markets after upward breakouts, do it often enough and perfectly, you'll make an average of 44%. Trade tall and wide patterns and you'll do almost 50% better, with gains averaging 64%.

[Table 56.6](#) shows volume-related statistics.

Volume trend. The table shows the volume trend, but the results are close to random. Don't discard a chart pattern because it has an unusual volume trend.

Rising/Falling volume. Three of four columns show better performance if volume recedes in the pattern.

Breakout day volume. In all four columns, we see performance improve if breakout day volume is above the 1-month average (heavy volume).
