

To use the measure rule, calculate the height by subtracting the lowest low reached in the bowl from the high reached on the right side of the scallop. For upward breakouts, add the height to the top of the scallop to get a target. For downward breakouts, subtract the height from the lowest low.

An example makes the calculation clear. Consider the ascending scallop that forms during late September as shown in [Figure 57.5](#). Apply the measure rule to this scallop by subtracting the formation base from the right side high. Point B shows the pattern's low at 12.50, and the right side high, point A, is 16. The difference of 3.50 is the height. Add the height to the right-side high (point A) to get the target price of 19.50. Price meets the target in late April (not shown on the chart). If the scallop breaks out downward, then subtract the difference from the scallop's low (point B) to get the target price. In such a case, the target would be 9 ($12.50 - 3.50$).
