

have been no Industrial Revolution without the harnessing of cheap carbon, found in coal, oil, and gas. Many of the companies supplying the ever-growing energy needs of our world have proved marvelous investments over most of this century.

But in the last quarter of this century a different theme has emerged. Twenty years ago I wrote that carbon's dominance was being challenged by a second chemical element, silicon. Our ability to place thousands of circuit elements on tiny silicon chips was creating extraordinary information-gathering and -sorting systems. Information processing was become cheaper and cheaper, while energy was rising in price. It was clear, even in the mid-seventies, that "the world will substitute information for energy."

---

The Information Revolution is the theme I've worked hardest on and that has worked hardest for me. It's a theme that never seems to give out.

---

That substitution identified a sensational long-term megatrend. Even in 1976 I thought it was kind of old news, but I have continued to invest in that trend ever since. The Information Revolution is the theme I've worked hardest on and that has worked hardest for me. I've practically made a career out of that one idea, since I've consistently built a large part of my portfolios around it. It's a theme that never seems to give out.
