

Despite all these events, 1987 did *not* mark the end of the bull market in stock prices as had been expected. The 8 years since then constitute a rare extension of the Fibonacci time length. As you can see by the preceding table, durations at Supercycle degree are usually off a bit from a perfect Fibonacci number of time units. The differences may not be random, though. It is curious that wave (IV) was one year short, as if to make up for the extra length of its cousin, wave (II). Perhaps the impulse waves are doing the same thing. Waves (I) and (III) were both short, so wave (V) may have been granted a license to extend.

A "B" Wave From 1987?

The list of market and social events presented above argue that, in some senses, the 1987 high acted as the orthodox top of the bull
