Suppose, you lead an organization with 100,000 people.

You want to improve your hiring guidelines for a job role having 15,000 people.

You can utilize a machine learning model to improve your hiring guidelines. It can truly surprise you with its findings. However, it will require clean data for 100 fields in order to provide advice on 10-15 parameters that truly impact your hiring process.

A good starting point would be to map the organizations from where you hire your high performers.

To derive this, you must have the profiles of your high performers. Even if you have a profile of your high performers, you might not be able to analyze it because everyone would have written the names of their organizations in different ways.

The name of an organization can be recorded as ABC, ABCL, ABC Ltd., ABC Limited, or Aditya Birla. Cleaning a single field is a nightmare and it is not a one time effort. As more people continue to join, you need to keep cleaning it. **Most machine learning models fail due to inadequate data management.**
