3. Monitors the metrics and their impact on outcome over a period of time.

4. Identifies trends, patterns, and insights to improve HR practices.

You may improve the quality of HR decisions (like identifying top performers) by leveraging HR analytics. HR analytics uses statistical tools like regression analysis and predictive modeling to analyze large volumes of data. Let's start with regression analysis first.

Regression Analysis

Regression analysis is a tool that shows the relationship between two or more variables. Variable is a parameter whose value is not fixed and can change. Suppose you have the opinion that long working hours cause attrition. In this case, both long working hours and attrition are variables.

The variables are of two types:

1. Dependent Variables -

The variables which are dependent on other variables are called dependent variables. Since attrition depends on long working hours, it means attrition is a dependent variable.

2. Independent Variable -

Variables for which you can change the value are called independent variables. You may change working hours, it means working hours is an independent variable.
