- Once you have formed VPC and validated your ideas, it's time to build a prototype based on the insights you get from VPC. A prototype is a primary version of your product that allows you to test its functions, design, and user experience before investing all the resources into making it. Also, develop an MVP, which is the minimum viable product.

It is the simplest version of your product that contains only the main features and characteristics necessary to address the key needs.

- MVP is used to get the product to early users so that you can gather feedback and iterate on your product based on real-world usage. It is a process where a product is being used by users for testing purposes and gathering feedback to check the performance of the product.

This will help you get the answers to questions like-

Does the product have value or not?

Should we continue to develop this product?

What are the problems?

What are the improvements that can be made to enhance the product?

The main purpose is to work on the feedback.

This is the essential part where improvements and iterations can be made in the product development process. It involves consistently enhancing and improving products based on feedback received and changing according to market conditions. These make your product valuable and competitive in the market to meet customer expectations.
