The tax bite matters: Consider a manager returning 30 percent a year. Yes, it's an amazing return, but the manager churns the portfolio consistently to generate these returns. After a 43.4 percent tax, this yields only 16.98 percent to his investors. Another manager makes 22.28 percent a year—quite an accomplishment—but this manager trades less frequently to lock in long-term capital gains. After tax, this managers' return is 16.98 percent. Finally, consider a buy and hold manager that generates 16.98 percent a year, but never sells or rebalances the portfolio. After tax, this manager still makes 16.98 percent. All three managers generate 16.98 percent after-tax returns, but the three managers have very different pretax results, and therefore offer vastly different security-selection skill levels. But that doesn't matter. In these cases, alpha is irrelevant—it is tax efficiency that matters.

Consider the following when it comes to taxes.

### **Tax Efficiency?**

How are returns taxed? Can this strategy be more tax-efficient? Why or why not? Can it ever be tax-efficient?
