

8.1.5 Enhanced Customisation

Fine-tuning allows customising the model's behaviour and output to align with specific user needs and preferences. By adjusting the model using targeted data and tailored instructions, fine-tuning enhances its relevance and performance in particular applications.

This process allows the model to better understand specialised contexts, jargon, and nuances, delivering more accurate and user-specific responses.

8.2 Retrieval-augmented Generation (RAG)

A process very similar to fine-tuning a model would be retrieval-augmented generation. Instead of training the model on a specific dataset, you ask the LLM to retrieve information from an authoritative source. So, you, the user, do not need to find and submit the data. The LLM will take over this task. However, there will be limits on how much you can customise the LLM through RAG.
