

Consequently, fine-tuning transforms a general-purpose model into a powerful tool that meets distinct requirements, significantly improving user satisfaction and effectiveness.

Consider the case of general physicians and orthopaedic doctors. General physicians can diagnose and treat patients suffering from a variety of ailments. However, only orthopaedics can treat particular bone or joint conditions because of their additional training. An even more extreme analogy would be that a neurosurgeon is better suited than general physicians to treat brain aneurysms.

Fine-tuning a model with a specific dataset can take longer than implementing the RAG process. However, once the model is trained, the fine-tuned model will be faster than the RAG LLM since the fine-tuned model does not need to search for data from authoritative sources for each prompt repeatedly.
