

Aspect	Fine-Tuning	Retrieval-Augmented Generation (RAG)
 Definition	Adjusting a pre-trained language model (LLM) on a specific dataset to improve performance on specialised tasks.	Combining retrieval mechanisms with generative models to enhance context and accuracy during response generation
 Data Requirement	Requires a labelled training dataset tailored to the specific tasks or domains	Utilises external knowledge bases or documents to fetch relevant information for retrieval
 Customisation	Offers high customisation, allowing the model to be finely tuned for particular tasks and domains	Customisation is achieved by integrating relevant retrieval components that provide additional context.
 Inference Speed	Faster inference after the complete fine-tuning process as the model is optimised for specific tasks.	Slower inference due to the additional step of retrieving relevant information during the generation process.
