

8.3.2 Data Processing

This is a crucial step before training your model to ensure that the data is in an optimal format for learning. If the data you collected in the previous step is not up to the mark, you can optimise it by performing the following tasks:

1 Cleaning – Remove Irrelevant, Erroneous or Duplicate Entries

This step helps to eliminate noise and inaccuracies that could adversely affect model performance. Cleaning also involves addressing missing values, correcting inconsistencies, and filtering unnecessary information.

3 Normalisation – Standardise the Text to Ensure Uniformity

This may include converting all text to lowercase and removing punctuation. You may also need to remove suffixes and rewrite words in their most basic form, i.e. stemming and lemmatising. Normalisation helps reduce data variability, making it easier for the model to generalise patterns.

Missing Values

Unstructured Data

Consistent Information

Structured Format
