

So, for this purpose, you will ask ChatGPT to act as a specialist in sentiment analysis and classify the text you share with it into positive, negative, and neutral sentiments in a tabular format.

Classify text into positive, negative, or neutral sentiments in a table.

 ChatGPT

Sure, I can help with that. Here's the sentiment analysis for each of the given texts:

Text	Sentiment
"Can you help me understand my current plan details?"	Neutral
"I'm experiencing some issues with my service, can you assist me?"	Negative
"How do I set up call forwarding on my phone?"	Neutral
"I want to upgrade my data plan, what are my options?"	Neutral
"What's the process for cancelling my subscription?"	Neutral
"I'm impressed with the speed of my internet connection, thank you!"	Positive
"I'd like to change my billing address, how can I do that?"	Neutral
"Is there a way to monitor my data usage in real-time?"	Neutral
"I'm having trouble accessing my voicemail, could you troubleshoot this for me?"	Negative
"I'd like to inquire about international calling rates."	Neutral

You can see that the classifications made by ChatGPT are pretty accurate. Why? Because ChatGPT and other AI tools are trained on vast amounts of data. So, they understand the sentiments of customers very easily.

In previous chapters, you have seen how ChatGPT can generate original text based on its prior training. So, these were some examples of primary use cases of what ChatGPT and various other LLMs can do.
