

By versatility, ChatGPT can work with various data types, from structured data like tables and spreadsheets to unstructured text data. This enables tasks such as text analytics, summarising large documents, and time-series analysis.

Some of the tasks that ChatGPT can currently do are exploratory data analysis (EDA), descriptive analysis, predictive analysis, and diagnostic and prescriptive analysis.

10.6.1 Exploratory data analysis (EDA)

If you submit a dataset to ChatGPT, it can tell its key characteristics and hidden patterns and uncover relationships between variables, i.e. perform exploratory data analysis (EDA) for you. Thus, you can get valuable insights into the dataset without performing extensive manual analysis. EDA is the first and most important step in any data science exercise.

10.6.2 Descriptive analysis

Descriptive analysis involves identifying outliers, summarising trends, and building a crisp but comprehensive description of all the observations in the dataset. ChatGPT enhances your ability to understand what's happening within the data by taking over this task.

10.6.3 Predictive analysis

ChatGPT can build various kinds of forecasts based on different types of data. It is equipped with multiple industry-standard predictive models and can deliver accurate projections.
