

1.8 What is Generative AI?

AI is the theory and development of computer systems to perform tasks normally requiring human intelligence. True AI is when computers start to act like humans and do tasks like humans without human involvement. But we are currently very far from this level of true AI.

As mentioned earlier, what we are currently using is ML.

ML gives computers the ability to learn without explicit programming. They learn by observing patterns in data. They learn by understanding hidden relationships between input and output variables, and eventually, they try to make sense of the data we give them using ML.

There are typically two types of ML- unsupervised and supervised. Supervised ML is when you give a lot of data where the inputs and outputs are labelled.

Let us assume that you want to predict the weather tomorrow. You can give your machine the data about the last 10 years of weather reports. Looking at the past data, the machine will try to identify a pattern that can be applied to predict the weather tomorrow. Machines will be able to do this because they have now been trained for this exact purpose. This is supervised ML.
