

For this purpose, enter a prompt saying,

My data looks like this: Flat 101, 123 Main Street, Springfield, 12345. I want the flat number, address and pin code in separate columns.

ChatGPT

1. Select the column containing your data (let's say it's column A).
2. Go to the "Data" tab in Excel's ribbon.
3. Click on "Text to Columns".
4. In the Wizard that appears, choose "Delimited" and click "Next".
5. Select "Comma" as the delimiter and click "Next".
6. In the "Column data format" step, you can choose the format for each column. Since you want the data in separate columns, you can leave it as "General" for all columns. Click "Finish".

This will split your data into separate columns based on the commas. Now, you will have Flat Number in one column, Address in another column, City in another column, and Pin Code in the last column.

Since you do not want a set of instructions but a spreadsheet formula, then edit your prompt to add this sentence:

I want a spreadsheet formula for the same.

ChatGPT

To extract the flat number, address, and pin code from the data string "Flat 101, 123 Main Street, Springfield, 12345" into separate columns in Excel, you can use a combination of Excel's built-in functions like MID, LEFT, RIGHT, FIND, and LEN. Here's how you can do it:

Assuming your data string is in cell A2, you can use the following formulas:

For Flat Number (assuming it's always "Flat" followed by a space and then the number):

excel

Copy code

```
=TRIM(MID(A2,1,FIND(", ",A2)-1))
```

This is a good example of why you need specific instructions for the desired results. After editing your prompt, this response you received.
