

Similarly, we can even use machines to predict the performance of sportsmen. A machine could tell us how many runs Dhoni or Kohli will make on a particular day. A machine can do so only because we have a lot of statistics with us. We have data about how many runs these players have scored so far, their scores on this particular ground, their scores as teammates and individuals, and their favourite scoring zones.

Supervised ML

Predicting Tommorrow’s Weather

Predicting Player’s Performance

Humans will take a lot of time to understand these patterns. Still, because machines can learn faster and find relationships in the data, they will make precise predictions about how likely a batsman is to score a certain number of runs.

This approach is called supervised ML, where data is labelled and organised, and the input and outputs are known.
